

Timing Constraints

- Event-triggering constraint
 - Periodic
 - Period
 - Jitter: Maximum deviation from the start of the period. Could be larger than period. Does not cause the period to drift
 - Min inter-arrival time: Minimum time between two consecutive events.
-

Figure 7.4: Example of a Periodic Event Triggering Constraint

AUTOSAR CP R19-11. "Specification of Timing Extensions," AUTOSAR_TPS_TimingExtensions, page 118.

- Sporadic (Generalisation of periodic; events can be absent)
 - Period (optional)
 - Jitter (optional)
 - Min/Max inter-arrival time: Minimum and maximum time between two consecutive events
-
- The diagram illustrates a sporadic event stream over time. The horizontal axis represents time, with vertical dashed lines marking event occurrences at times t , $t+j$, $t+j'$, and $t+2$. The intervals between consecutive events are labeled: Min iAT (minimum inter-arrival time), Max iAT (maximum inter-arrival time), and jitter (the difference between consecutive arrival times). The period is also indicated.
- Legend:
- ↓ Event Occurrence
 - Min iAT Minimum Inter-Arrival Time
 - Max iAT Maximum Inter-Arrival Time
 - jitter Jitter

Figure 7.10: Parameters characterizing the Sporadic Event Triggering

AUTOSAR CP R19-11. "Specification of Timing Extensions," AUTOSAR_TPS_TimingExtensions, page 122.

- o Concrete pattern (Precisely known event occurrences)
 - Pattern period (optional)
 - Pattern jitter (optional)
 - Pattern length: Duration of the event pattern
 - Offset: Set of event occurrences, defined as timing offsets into the pattern length

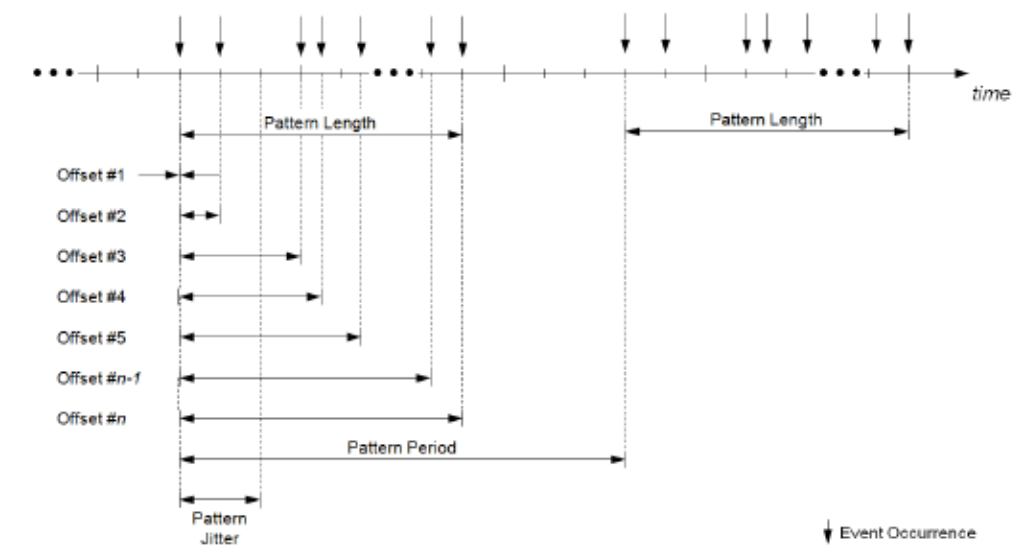

Figure 7.13: Parameters characterizing the Concrete Pattern Event Triggering when periodically being repeated

AUTOSAR CP R19-11. "Specification of Timing Extensions," AUTOSAR_TPS_TimingExtensions, page 124.

- Burst Pattern (Typically used to model worst case activation scenarios)
 - Pattern period (optional)
 - Pattern jitter (optional)
 - Min number of occurrences (optional): Min number of times the event has to occur during the pattern itself
 - Max number of occurrences: Max number of times the event can occur during the pattern itself
 - Min inter-arrival time
 - Pattern length
-
- Maximum Number of Occurrences = 7
- Minimum Number of Occurrences = 5
- Pattern Length
- Pattern Period
- Pattern Jitter
- Minimum Inter-Arrival Time
- time
- Fixed Occurrence

Figure 7.16: Parameters characterizing the Burst Pattern Event Triggering when periodically being repeated

AUTOSAR CP R19-11. "Specification of Timing Extensions," AUTOSAR_TPS_TimingExtensions, page 128.

- Arbitrary (Abstracts the event occurrences captured by data logging tools)
 - Min/Max distance: Minimum and maximum during which n number of events must occur. A min and max are defined for $n = 2, 3, 4, \dots$ event occurrences
 - Confidence Interval: Probability that the min/max distances are observed
-
- min Δ 2 max Δ 2 min Δ 3 max Δ 3 min Δ 4 max Δ 4 min Δ 5 max Δ 5
- Time
- min Δ n Least minimum inter-arrival time between n subsequent occurrences of the event E and $n = \{2, 3, 4, \dots\}$
 - max Δ n Major maximum inter-arrival time between n subsequent occurrences of the event E and $n = \{2, 3, 4, \dots\}$
 - Event Occurrences

page 131.

-
- Figure 1: Latency constraint (on event chains). The diagram shows three tasks (Task A, Task B, Task C) and their corresponding stimulus and response times across 13 time steps. Task A (blue) has a latency constraint of 3, Task B (red) has a latency constraint of 2, and Task C (green) has a latency constraint of 1. The legend indicates: orange square for Task executed, blue square for Task presented, red square for Task activation, green square for Data flow, and red circle for Data is overwritten before read.

Figure 7.19: Loss and duplication of data due to under- and oversampling

AUTOSAR CP R19-11. "Specification of Timing Extensions," AUTOSAR_TPS_TimingExtensions page 132.

- Age constraint (on data received at a port)
 - Scope: Timed event
 - Min/Max: Minimum and maximum age of an event
 - During design, the sender of data may be unknown, but still an age constraint is needed on the receiver port
 - Once the system is more developed and the sender becomes known, a timing event chain can be specified to refine the age constraint
 - Synchronisation timing constraint
 - Scope: Timed events and timed event chains
 - Event occurrence kind: Single or multiple occurrences of an event within a given time interval
 - Synchronisation constraint type: Stimulus or response of event chains will occur simultaneously, or events will occur simultaneously.
 - Tolerance: Maximum time interval that the synchronised events are to occur simultaneously
 - Establish a consistent time base in a distributed environment
-
- Diagram illustrating a Synchronisation timing constraint:
- Timeline: $S4, S2, S3, S1, R$ (events) vs. $time$ (axis).
 - Legend:
 - S# Stimulus Event
 - R Response Event
 - ↓ Event Occurrence
 - Tolerance: Indicated by a double-headed arrow between $S4$ and $S1$, representing the maximum time interval for simultaneous occurrence.

Figure 7.23: Parameters characterizing the Synchronization Timing Constraint imposed on the stimulus events of event chains.

S	R3	R4	R2	R1
---	----	----	----	----

-
- Figure 7.26 illustrates the parameters characterizing the Synchronization Timing Constraint imposed on the response events of event chains. The diagram shows a timeline with stimulus events (S) and response events (R#). A tolerance window is defined between a stimulus event and a response event. Below, a specific example shows stimulus events E1, E3, E4, E2, E5 and their corresponding response events, with a tolerance window indicated.

- **Source:** The executable entities that should finish executing before the synchronisation point
- **Target:** The executable entity that should start executing after the synchronisation point

- Specify that a group of executable entities can only execute once the execution of another group of executable entities have all finished, thus, the synchronisation point is logical
- **Offspring timing constraint**
 - Source: Timing event that the target event will be synchronized with
 - Target: Timing event that will occur after the source event
 - Min/Max: Minimum and maximum offset that the target should occur relative to the source event
 - Bound: the time offset between two timing events, even if there is no functional dependency between the source and target
- **Execution order constraint**
 - Execution order type: Ordinary (sequence of executable entities), Hierarchical (nesting of execution orders: allowed, or repetitive (sets of executable order constraints that are repeated))
 - Ordered elements: List of executable entities to order
 - When an event occurs, the entities will be executed in their defined order
- **Execution time constraint**
 - Component and Executable: The executable and its parent component to which this execution time constraint applies
 - Execution time type: Gross (time without interruption, but with external calls) or net (time without interruption and without external calls) execution time
 - Min/Max: Minimum and maximum allowed execution time
 - Bound the allowed execution time of an executable entity

Use Cases

- **End-to-end timing in control systems**
 - Identify all the event-chains from sensor, controller, to actuator.
 - For closed-loop systems, identify and describe how the feedback loops are dealt.
 - Analyse the end-to-end delays for the event-chains.
 - Analyse the impact that various execution order and scheduling order have on timing properties.
 - Select the most reasonable variant.
- **Synchronisation of concurrent event chains that share a common functional context**
 - **Sensor data fusion:** Combine sophisticated time-correlated sensor information from different sensors. For example, adaptive control of cruise radar and wheel data, or parking distance control fuses data from sensors of the same type to build an overall environment model.
 - **Actuator synchronisation:** Operate intelligent actuators simultaneously. For example, synchronous door opening, hazard warning lights, or anti-lock braking system.
 - **De-synchronisation:** Reduce or remove reading delays between tasks by synchronising the gateway with its connected buses.
- **Early prediction of timing behaviour during the design phase**
 - Analyse the impact of adding a component: Component to be added must provide its own timing information. The component together with the existing system will impose timing constraints on each other, e.g., end-to-end response times or synchronisation.
 - **Hardware dimensioning:** Cost-effective hardware configurations that just satisfy the system's timing constraints can be chosen early on in the design phase.
 - **SW/ECU topology:** Choose the right topology, e.g., minimise latencies, minimise data transfers, minimise data loads, or balance out workloads.
